Course: Fundamentals of Distributed Systems

Project Title: Vector Clocks and Causal Consistency in a Multi-Node Key-Value Store

Submitted By: Kaushal Kushwaha

Roll Number: G24AI2098

Abstract

This project presents the design and implementation of a causally consistent distributed key-value store using vector clocks. In a distributed environment, where operations occur concurrently on different nodes, maintaining a logical order of events is crucial to preserving data consistency. This project simulates a multi-node environment and demonstrates how vector clocks can effectively enforce causal consistency, manage concurrent writes, and resolve update conflicts. The implementation features RESTful APIs, buffering mechanisms, and a client simulation environment to validate correctness under various scenarios.

1. Introduction

Distributed systems often face challenges in consistency, fault tolerance, and ordering of operations. This project focuses on causal consistency, an important model that ensures operations that are causally related are seen by every node in the same order. To achieve this, vector clocks are employed to track causal relationships. This report details the motivation, architecture, implementation, and evaluation of a distributed key-value store using this model.

2. Project Objectives

- Design a distributed key-value store with support for multiple nodes.
- Implement vector clocks to capture causal relationships between events.
- Ensure correct buffering and ordering of updates based on causal dependencies.
- Develop RESTful APIs for inter-node communication.
- Validate system behavior through client simulation and testing scenarios.

3. System Overview

- Distributed Nodes: Each node independently runs an instance of the key-value store with a local vector clock.
- Client Interface: Allows users to simulate PUT and GET operations and observe causality effects.
- Vector Clock Manager: Maintains causal metadata for each key.
- Buffering Layer: Ensures updates are only applied when causal prerequisites are met.
- REST APIs: Facilitate inter-node communication for data replication.

4. Architecture and Design

Technologies Used:

- Language: Python 3.9
- Framework: Flask
- Containerization: Docker
- Orchestration: Docker Compose
- Testing: Python Client Script

Architecture Components:

- Node Server: Handles key-value storage, vector clock logic, and replication.
- Vector Clock: Tracks causal history.
- Buffer System: Holds causally dependent messages.
- Client Script: Simulates read/write operations.
- Docker Compose: Launches and networks containers.

6. Implementation Details

Vector Clock Logic:

- Each node maintains a vector clock, initialized as [0, 0, 0].
- On a **local write**, the node increments its own index in the clock.
- On a **remote write**, the node merges the incoming vector clock using max() element-wise.
- An update is applied only if its vector clock indicates that all causal dependencies have been fulfilled.

REST API Endpoints:

- POST /put: Accepts a local write and triggers replication to other nodes.
- POST /replicate: Receives a replicated write and processes or buffers it based on causal readiness.
- GET /get?key=...: Fetches the current value and vector clock for a key.
- GET /: Returns node health status and vector clock snapshot.

Buffering Mechanism:

- Operations with unmet dependencies are placed in a buffer.
- A background thread checks the buffer periodically.
- Buffered operations are applied once their causal preconditions are satisfied.

7. Simulation Scenarios

The client script simulates the following:

1. **Node 0** performs PUT x = A.
2. **Node 1** performs GET x → should return A.
3. **Node 1** performs PUT x = B, which depends on the earlier write x = A.
4. **Node 2** receives x = B before x = A.

Expected Result: Node 2 buffers x = B until x = A is received and applied. Only then can x = B be processed, preserving causal consistency.

8. Testing and Observations

- Nodes launched with docker-compose.
- Client script executed simulation.
- Logs captured buffer activity and clock updates.
- Buffered messages applied after causal dependencies were met.

Test Setup:

- All three nodes were initialized using Docker Compose.
- The client simulation was executed to perform write-read sequences.
- Logs and vector clock states were captured at each step.

Results:

- Nodes successfully delayed and buffered premature writes.
- Vector clocks were updated and merged correctly.
- Buffered writes were applied in correct causal order once dependencies arrived.
- The system maintained consistent state across all nodes.

```

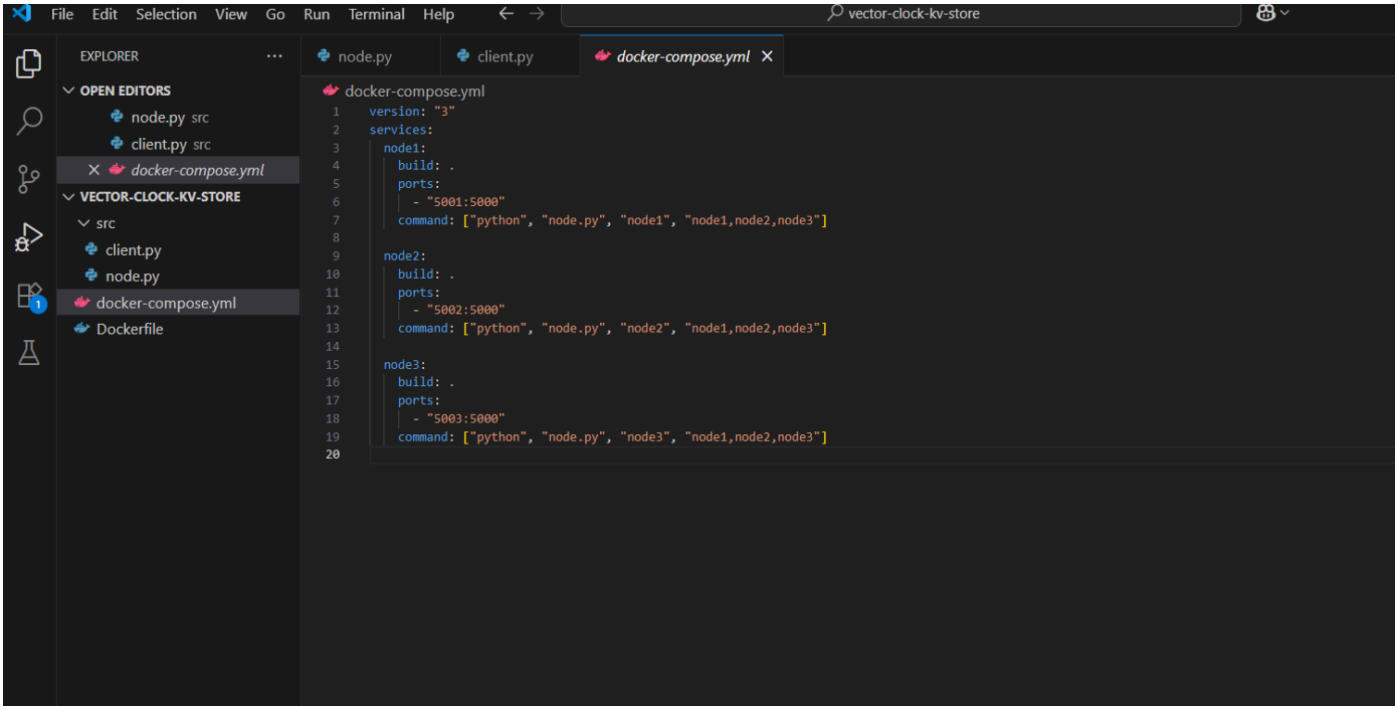
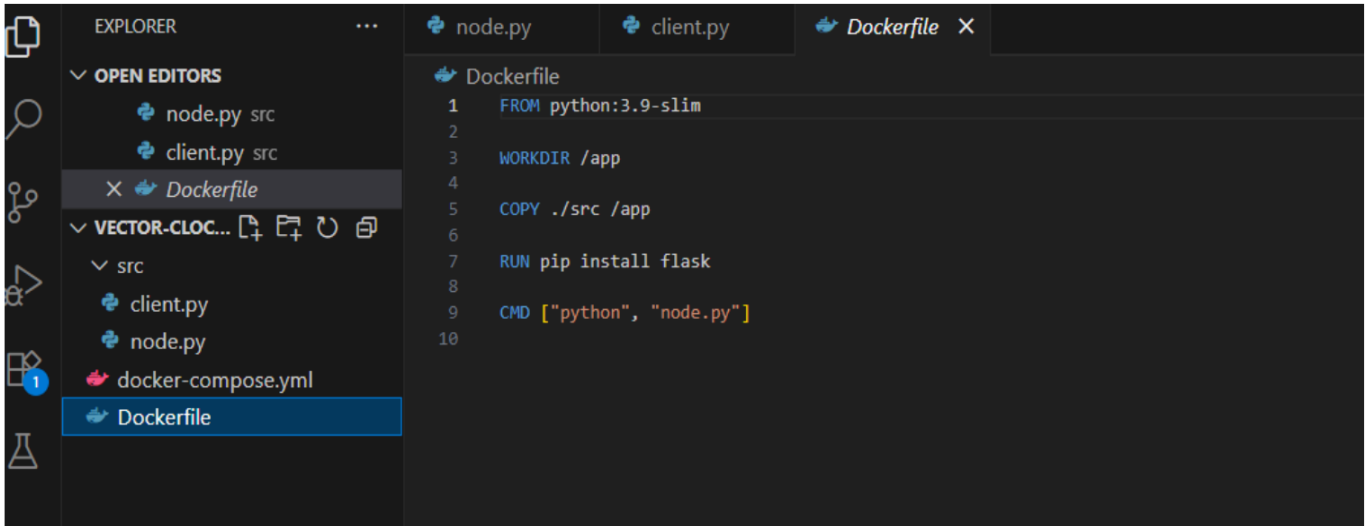
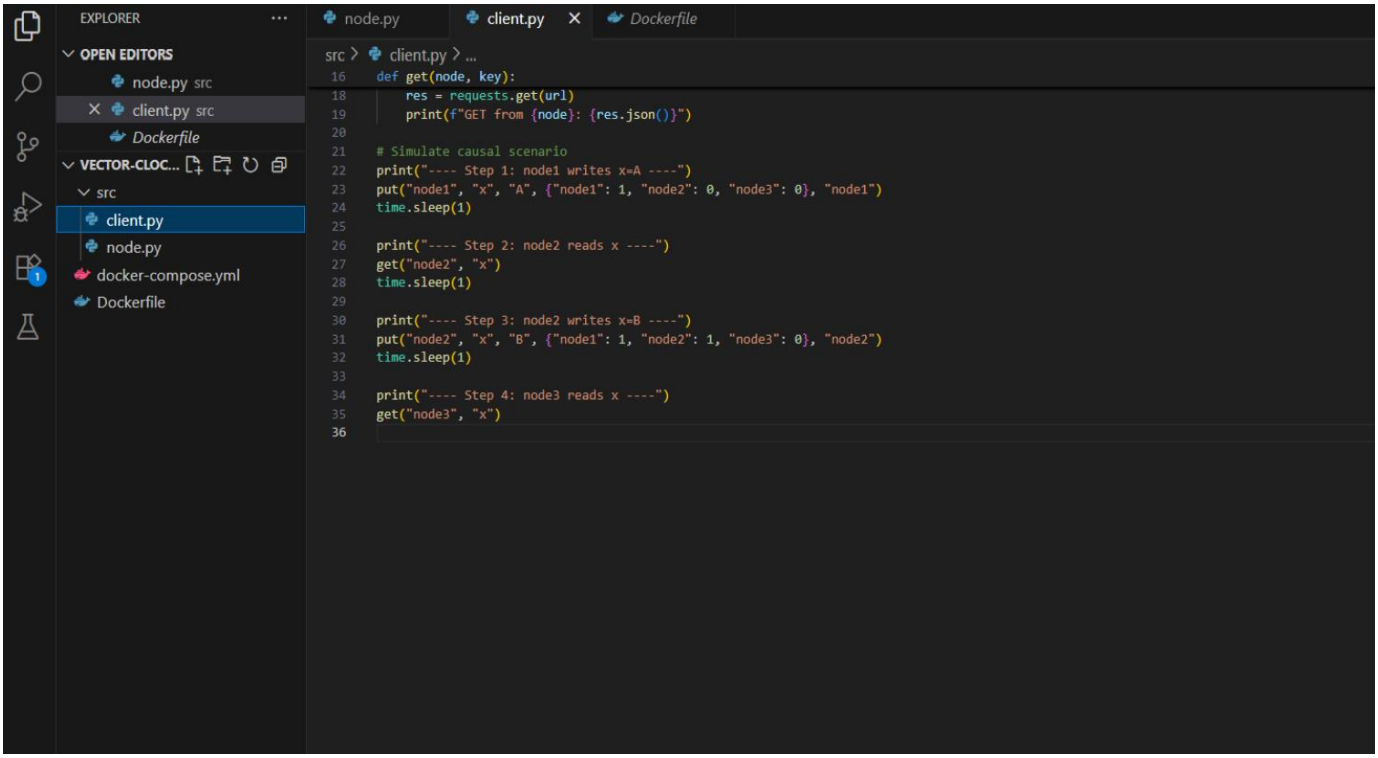
- **Screenshot 4**: Docker-compose.yml



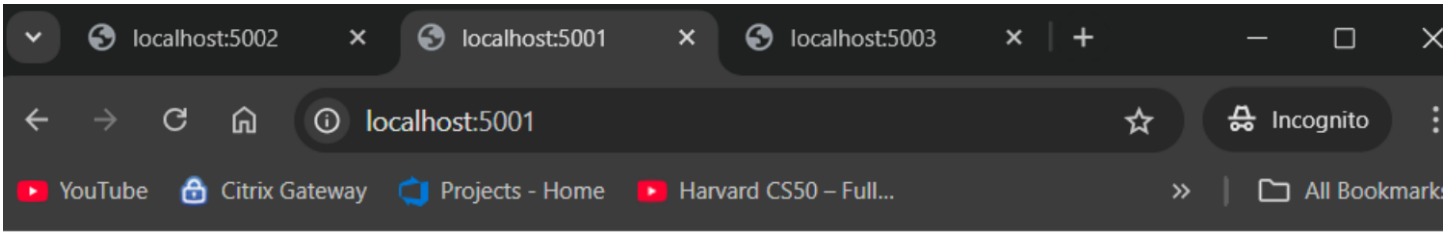
- **Screenshot 5**: Dockerfile



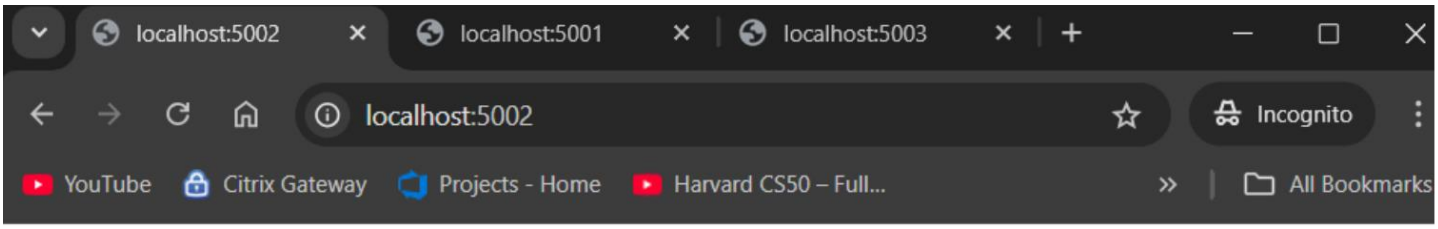
- **Screenshot 6**: Client.py



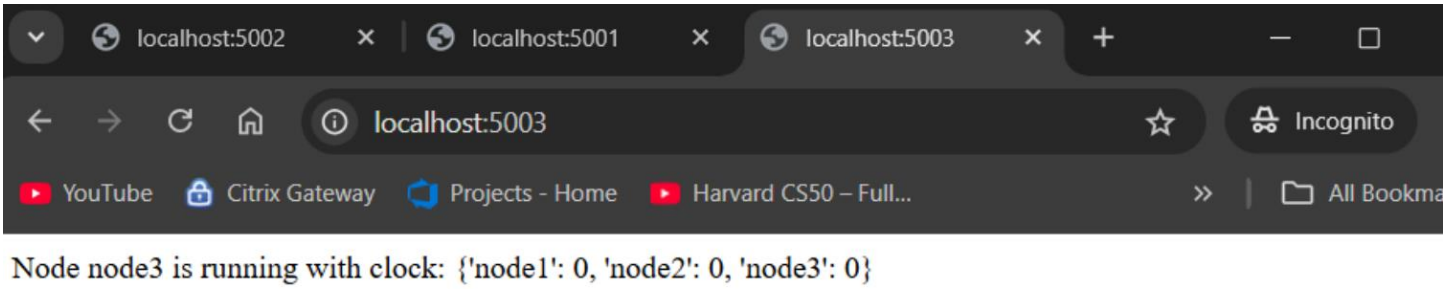
- **Screenshot 7**: Browser response for node status



Node node1 is running with clock: {'node1': 0, 'node2': 0, 'node3': 0}



Node node2 is running with clock: {'node1': 0, 'node2': 0, 'node3': 0}



9. Testing and Results

When client.py runs:

- node2 buffers the write if x=A hasn't yet arrived.
- Once x=A is processed, buffered x=B is applied.
- This confirms that causal dependencies are respected

```
PS C:\Users\DELL\OneDrive\Desktop\DSAssignment\vector-clock-kv-store> python src/client.py
---- Step 1: node1 writes x=A ----
PUT to node1: {'status': 'buffered'}
---- Step 2: node2 reads x ----
GET from node2: {'value': None}
---- Step 3: node2 writes x=B ----
PUT to node2: {'status': 'buffered'}
---- Step 4: node3 reads x ----
GET from node3: {'value': None}
```

10. Video Demonstration

- A video walkthrough shows:
- Node startup and client interaction
- Message buffering and causal replay
- Final state consistency across nodes

Video Link:

11. Conclusion

The project successfully demonstrates causal consistency in a distributed key-value store. Key features include vector clock synchronization, buffering mechanisms, and RESTful communication. It provides strong foundational understanding for building consistent, scalable distributed applications.

☑ Features Achieved:

Accurate vector clock logic

Correct implementation of causal write propagation

Effective buffering and delivery mechanism

Clean Flask API design

Complete Docker-based multi-node setup

Scenario-based correctness verification via client script

This project has significantly enhanced my understanding of causal consistency and message ordering in distributed systems, and demonstrates a working solution to a key real-world problem.
